Plant Cell Structure

Plant Cell

Parts of the Plant Cell

Cell Wall:

Ridged outer layer of a plant cell

I'm a brick wall.

Cell Membrane:

Controls what comes into and out of a cell;
found in plant and animal cells

Members only
can come and go.

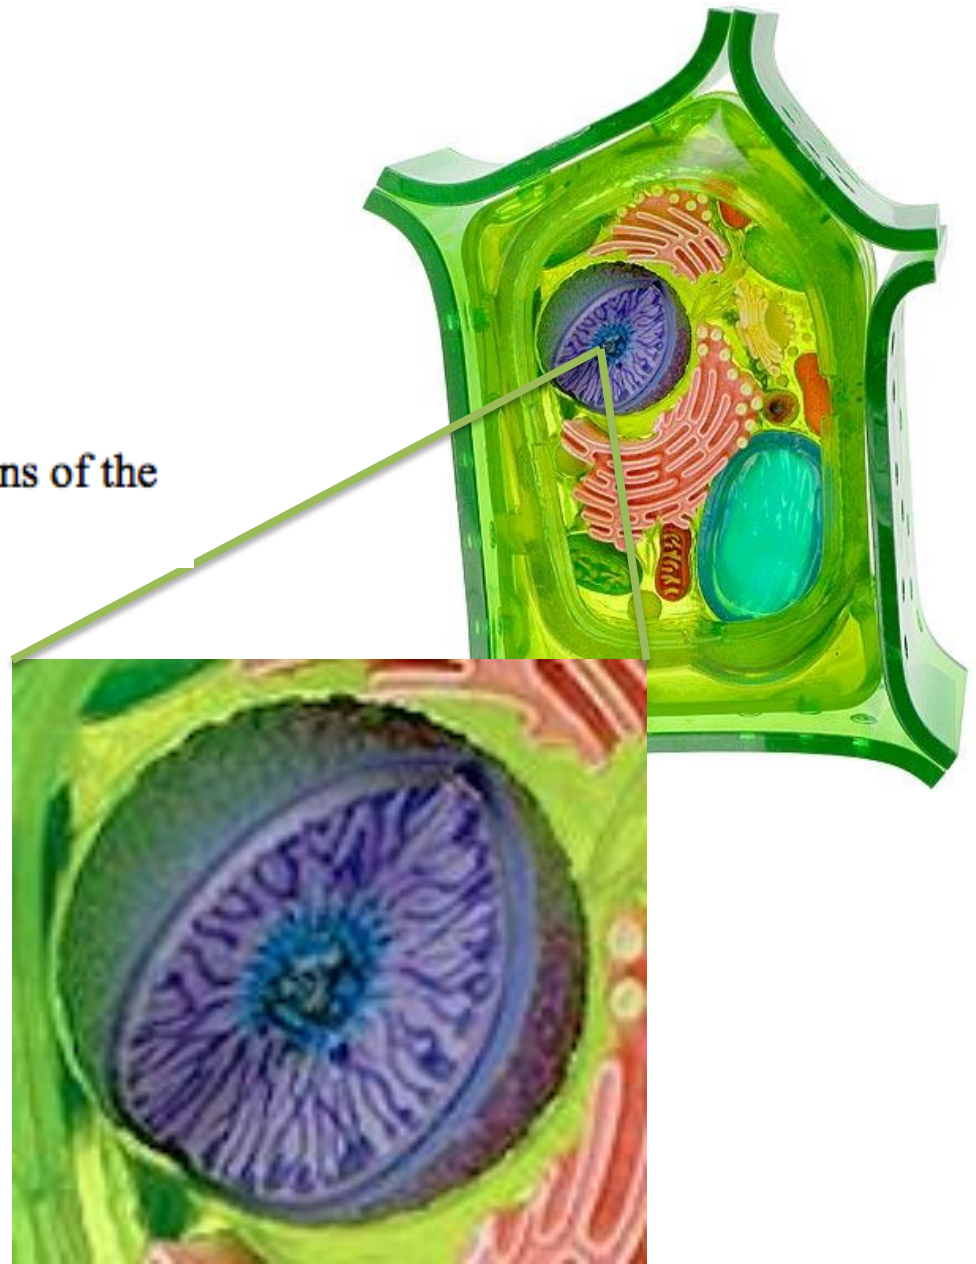

Parts of the Plant Cell

Nucleus:

Contains DNA, which controls the functions of the cell and production of proteins

I'm the
control center.

Parts of the Plant Cell

Endoplasmic Reticulum:

Has passageways that carry proteins and other materials from one part of the cell to another

I'm a
transportER.

Rough ER: with ribosomes

Smooth ER: without ribosomes

Parts of the Plant Cell

Golgi Bodies:

Receives proteins & materials from the ER,
packages them, & distributes them

I'm a
"GOLden" packer.

Parts of the Plant

Mitochondria:

Produces the energy a cell needs to carry out its functions

I am a "mighty" power house.

Vacuole:

Stores food, water, wastes, and other materials

I'll store anything,
(Hint: Vacuum Bags)

Parts of the Plant Cell

Chloroplasts-

Captures energy from the sunlight and uses it to produce food in a plant cells

Make me something
sweet to eat

A close-up photograph of a green leaf, showing a dense network of veins. The veins are a lighter green color, contrasting with the darker green of the leaf tissue. The veins form a complex, branching pattern across the entire surface of the leaf. The lighting is even, highlighting the texture and structure of the leaf's vascular system.

Photosynthesis

How and Why do Plants Make Food?

“Photo”= light

“Synthesis”= putting together

Plants need food but they do not have to wait on people or animals to provide for them. Most plants are able to make their own food whenever they need it.

This is done using light and the process is called

photosynthesis.

How do plants do this?

- To make food, plants need:
 - Water
 - Sunlight
 - Carbon Dioxide (CO₂)
- Results in: Glucose & Oxygen

carbon dioxide + water $\xrightarrow{\text{sunlight}}$ glucose + oxygen

Photosynthesis

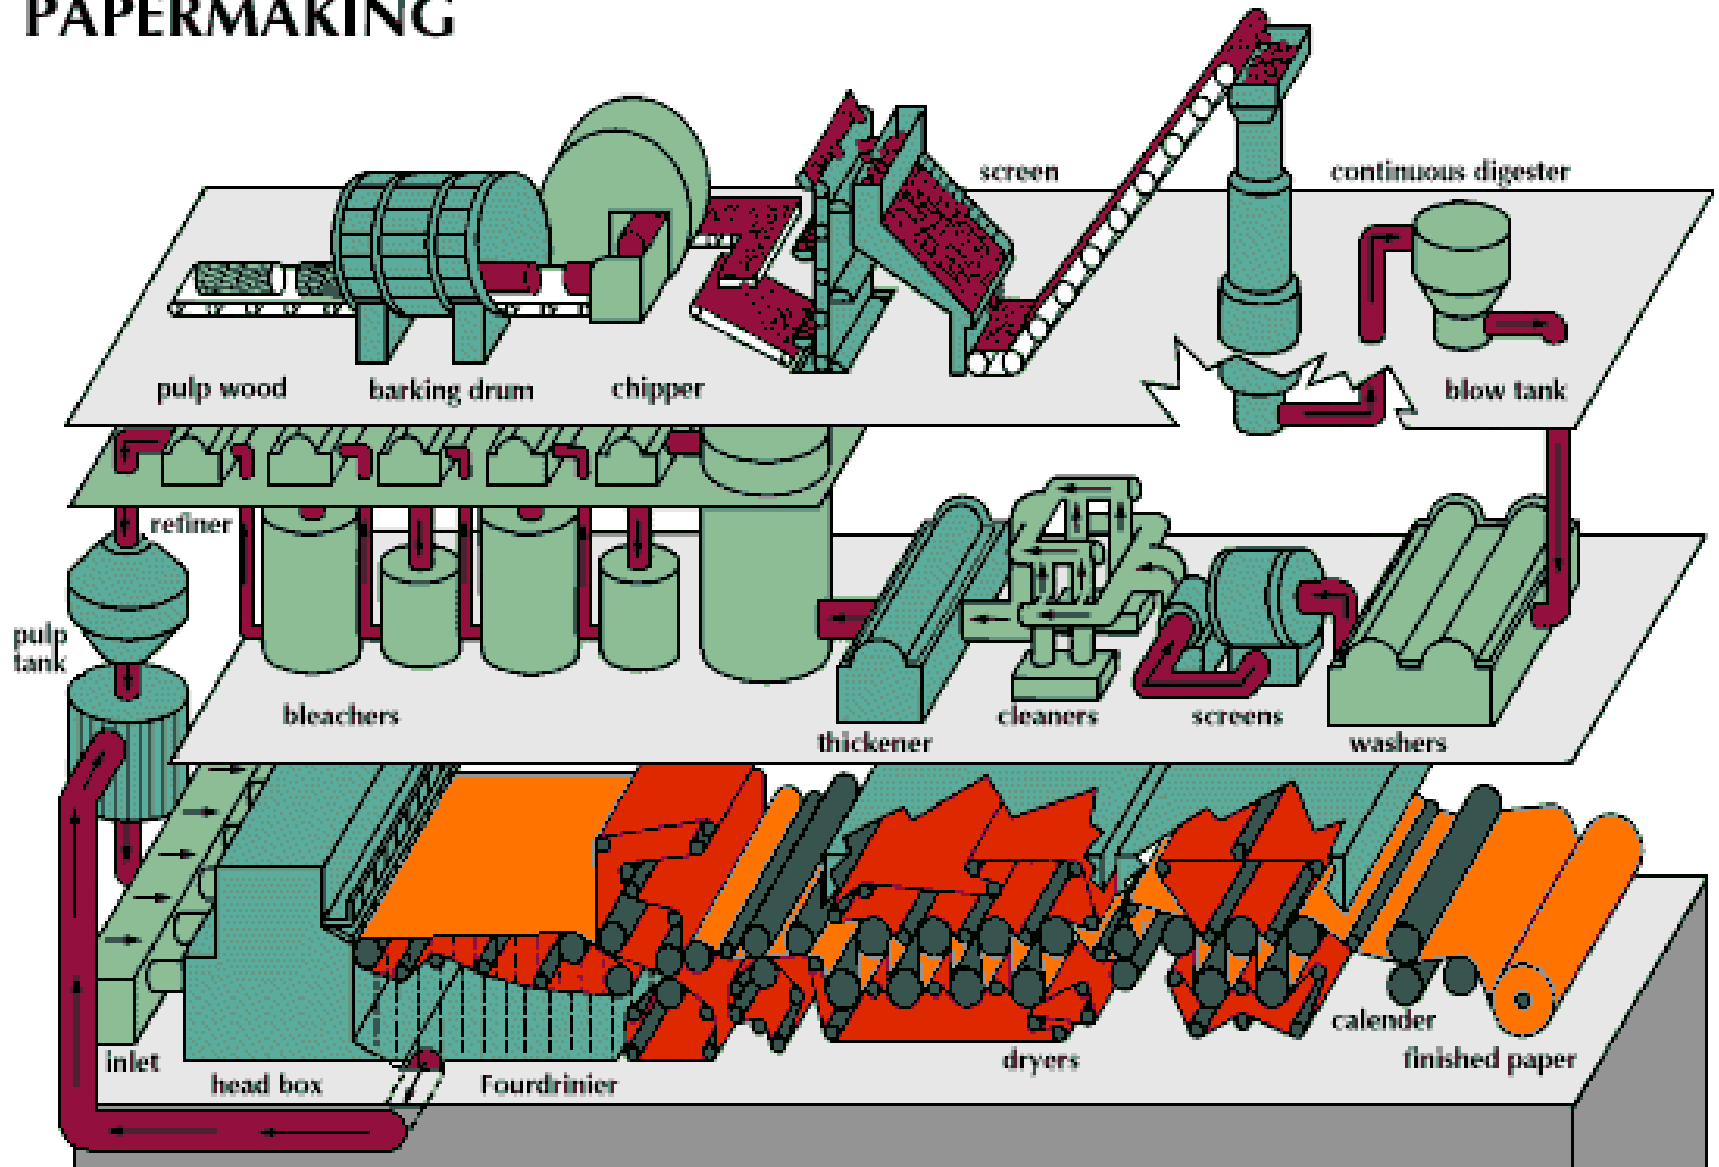

Why do we need Plants?

- They provide a source of food and energy for animals and humans.
- They provide oxygen for us to breathe.
- They provide many useful products:
 - Building materials
 - Medicine
 - Clothing
 - Paper

Using Trees to Make Paper

- The wood from trees is chopped up into small pieces
- The wood and fibers (which contains **cellulose**) are then boiled until it is a slush called “pulp”
- The pulp is then poured onto a fine mesh and water is drained and pressed
- Once dried, paper is formed

PAPERMAKING

The background of the image is a close-up, top-down view of a large pile of paper scraps and leaves. The paper is a light cream or off-white color, and it is heavily mixed with various pieces of green and brown leaves and twigs. The leaves are of different shapes and sizes, some appearing fresh and vibrant green, while others are dried and brown. The overall texture is rough and organic, suggesting a natural or recycled paper-making process.

**Now WE are
going to make
PAPER!**

**How Small is the Nano in
Trees?**

What do you see?

What do you think this would look like at the nanoscale level?

What exactly does nanoscale mean?

What is Nano?
nanometer = one billionth of a meter

About a billion blades of grass in
Jordan Hare stadium

A human hair is about 100,000
times bigger than 1 nm !

human hair ~ 100,000 nm
www.nisenet.org

Things are different at the nanoscale. Size and shape determine properties such as color

Cellulose Nanocrystals

Forest
Kilometers (Km)

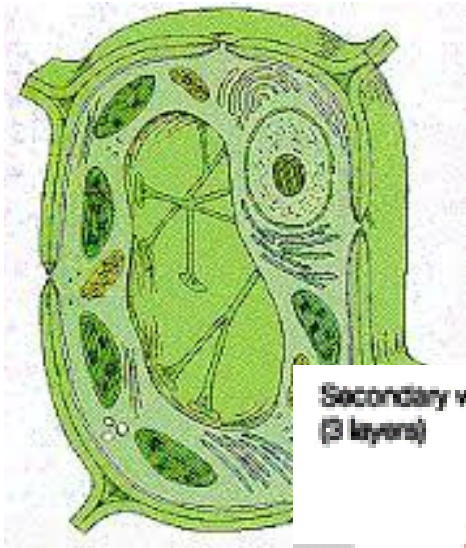

Tree
Meters (m)

Branch/twig
Centimeters (cm)

Width of Bark
Millimeters (mm)

Plant Cell
Micrometers (μm)

Fibers
Micrometers (μm)

Fibrils
Nanometers (nm)

Cellulose Nanocrystals
Nanometers (nm)

A scanning electron micrograph (SEM) showing a dense network of cellulose nanocrystals. The nanocrystals are thin, rod-like structures that vary in length and orientation. Some are colored in shades of orange and yellow, while others are green. The background is dark, making the nanocrystals stand out. The text "Cellulose Nanocrystal Activity" is overlaid in the center in a bright green color.

Cellulose Nanocrystal Activity

Cellulose Nanocrystals

Cellulose Nanocrystals

Cellulose Nanocrystals

Why do we see the colors when we look at the cellulose?

We can NOT see the individual nanocrystals.

However, the **size and shape** of these nanocrystals determine what colors we see in the microscope!

Photo courtesy of Shannon Bales and Rachel Bostic

Why are there different colors of light?

- There are different colors of light because light waves have different wavelengths

Why do these crystals look so colorful?

Remember:

Things are different at the nanoscale. Size and shape determine properties such as **color**.

We also see these colors because of the **interference** of different wavelengths of light.

What is Interference?

Definition:

- **Interference** is the overlapping of two or more waves resulting in a new wave pattern.

2 Types:

Constructive interference

Destructive interference

- Light hits the nanocrystal material and splits into 2 different waves traveling at 2 different speeds
- The rays will then exit the material at different speeds causing **interference**
- Different color wavelengths interfere differently
- Some wavelengths interfere **constructively** and some interfere **destructively**, therefore causing different colors to be seen
